IBIS AMI Modeling Challenges

High speed IO design is extremely complicated.

- Heavy equalization scheme is adopted as interfaces get faster.
- Prefabricated EQ blocks had been utilized from serdes tool box.

Customer demands qualified models in an early design stage.

- IBIS AMI model is the best known method to capture buffer characteristics.
- Projected design parameters are easily tunable through serdes tool box prior to the final design release.

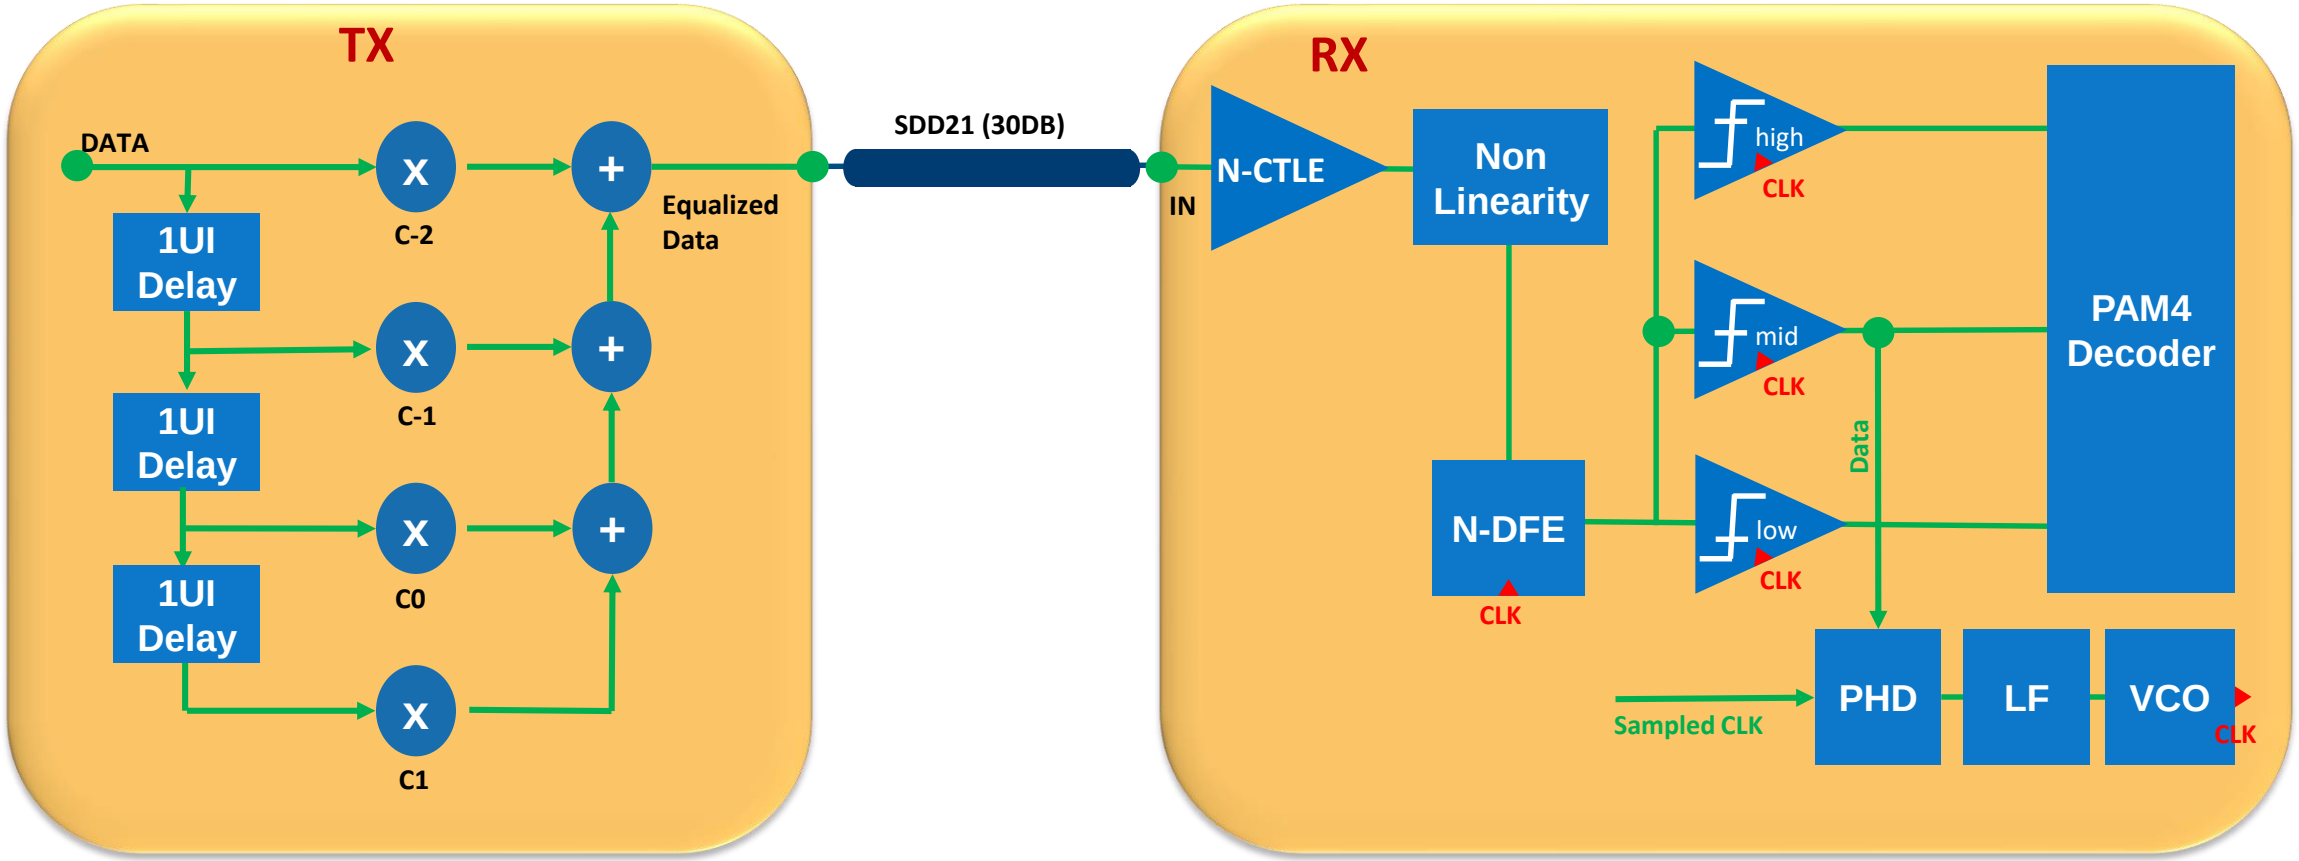
No standard or solid IBIS modeling methods.

- Achieving both IBIS model accuracy and efficiency is crucial.
- This paper demonstrates the cost efficient way to address this issue by using serdes tool box templates.

Long simulation time

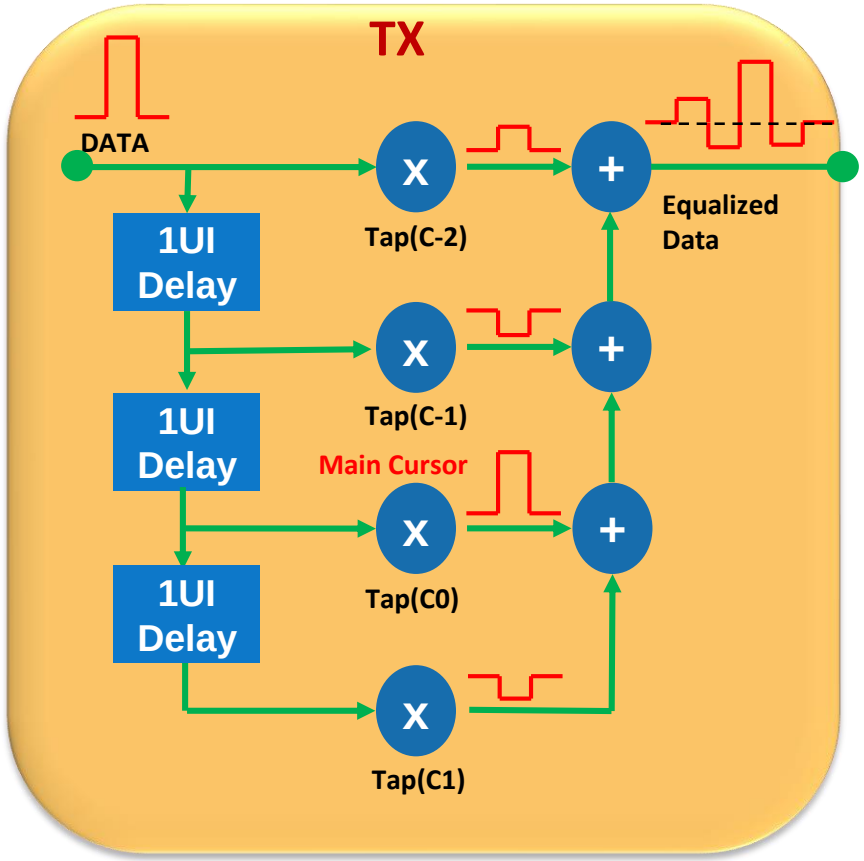
- Long simulation time due to design and adaptation complexity.
- IBIS AMI Model should capture circuit characteristics accurately and improve run time significantly.

Highlevel Pam4 architecture



Our goal is to achieve a high quality of AMI model from the complex design!

TX EQUALIZATION MODELING



- Two pre-taps and one post-tap

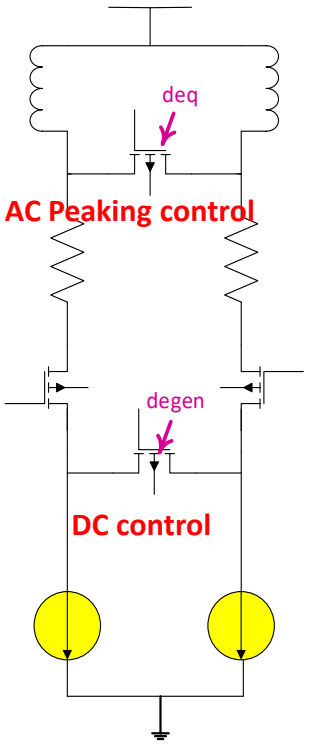
- C-2 & C0 are positive.
- C-2 & C1 are negative.

- Range/Graduality are modeled

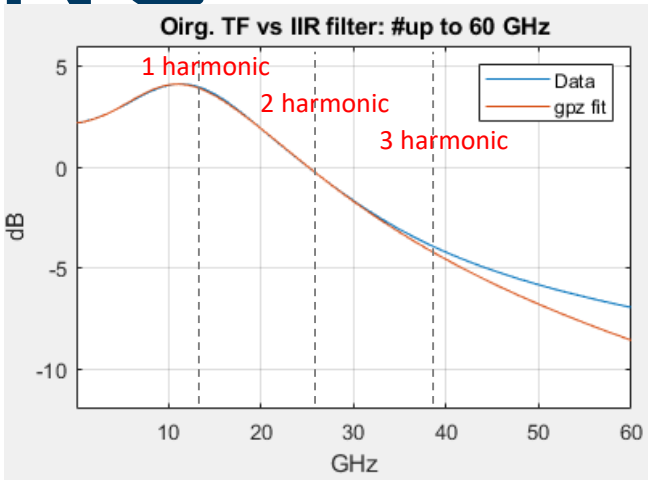
- Tap(C-2) = C-2 * step (C-2 is integer)
- Tap(C-1) = C-1 * step (C-1 is integer)
- Tap(C1) = C1 * step (C1 is integer)
- **Tap(C0) = 1 – abs(Tap(C-2)) – abs(Tap(C-1)) – abs(Tap(C1))**

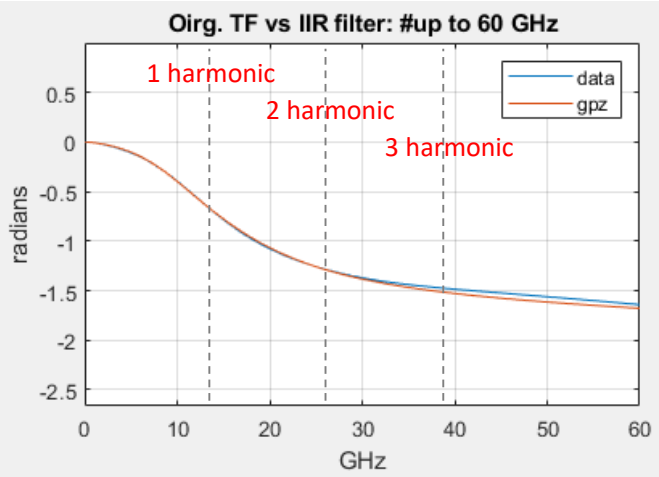
- Works for get_wave & init.

Ctle MODELING



N-CTLE





- Excellent correlation up to the 3rd harmonic

- Most energy is concentrated up to the 3rd harmonic.

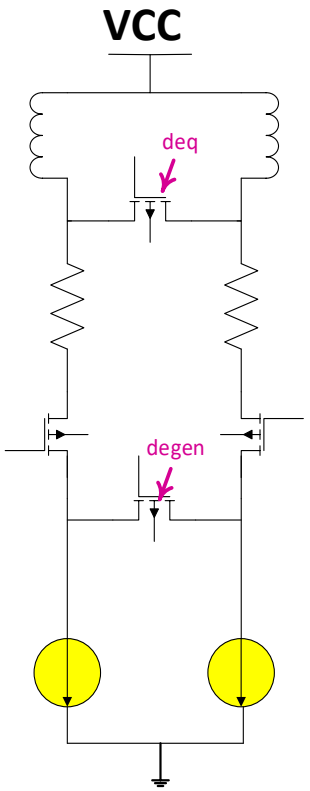
- MATLAB functions

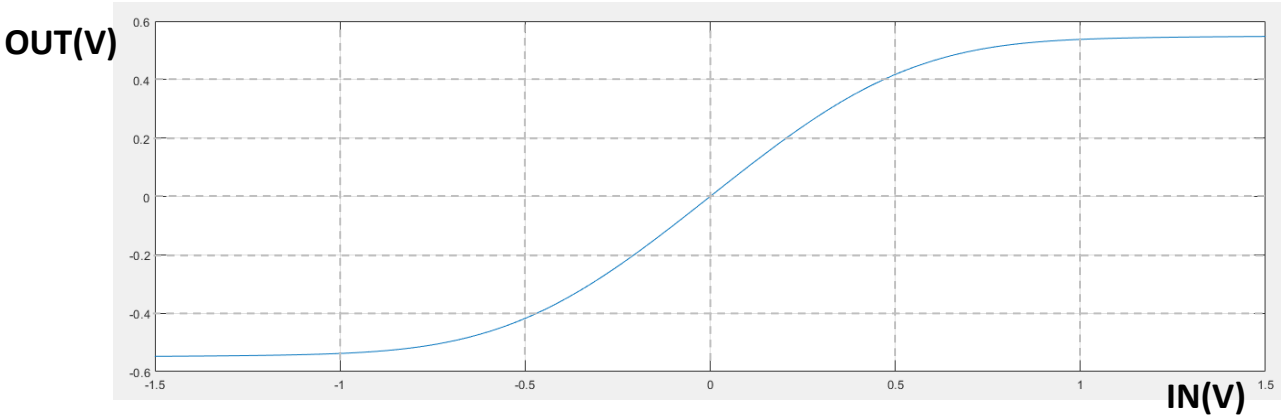
- Rationalfit, Freqresp (frequency response of a rational function)
- residue_rat_fit, getGPZ (Gain, pole and zero format) – custom scripts

- A significant amount of CTLE characteristics.

- ~900 CTLE curves, # of boosting stages.
- ~32 or 64 controls on each stage, 6 corner cases

Non-linearity MODELING





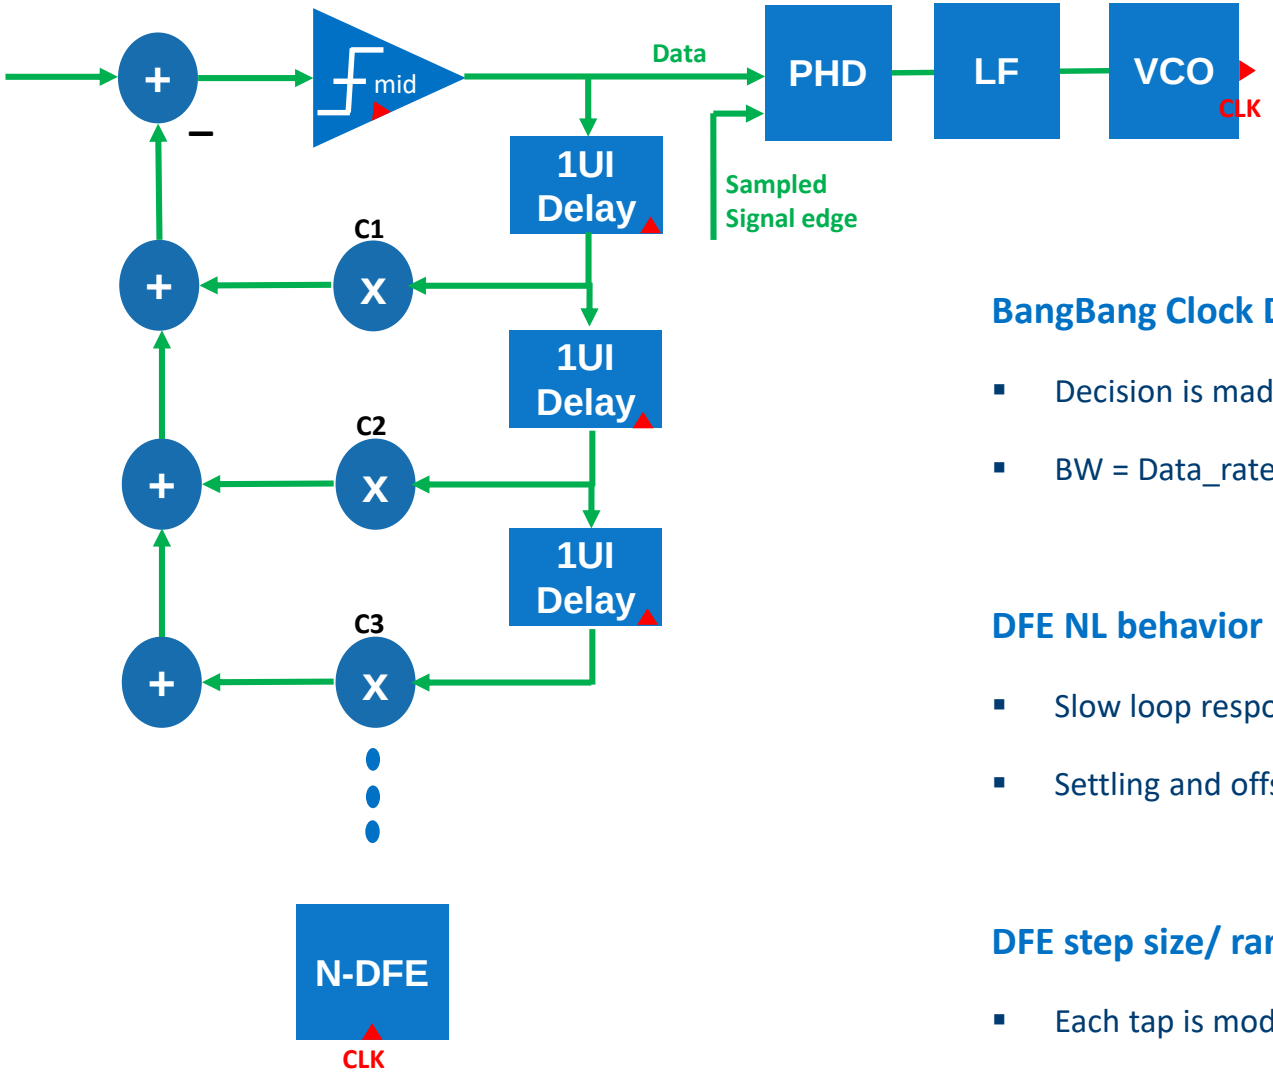
- Large signal response of amplification stage.

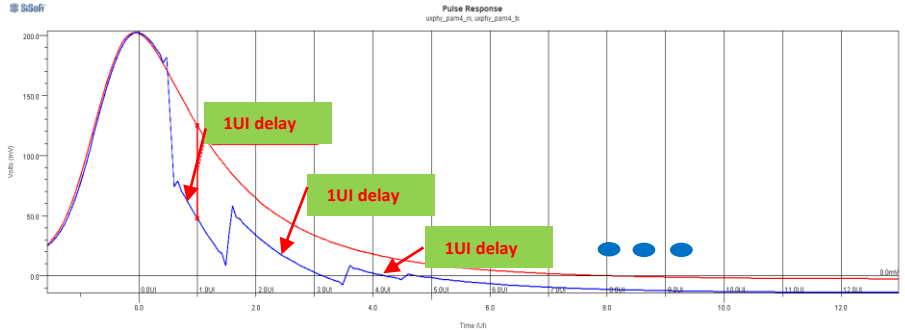
- CTLE TF is a small signal analysis.
- Swing is limited by amplifier headroom clamping.
- Critical to capture the circuit limitation.

- A significant amount of NL characteristics.

- ~300 non-linearity curves, # of boosting stages.
- Around 3 bit (8 selects) controls on each stage, 6 corner cases.

DFE/CDR MODELING





BangBang Clock Data Recovery

- Decision is made based on early or late clock to input data.
- BW = Data_rate * **CDR_Step** / Sample_rate

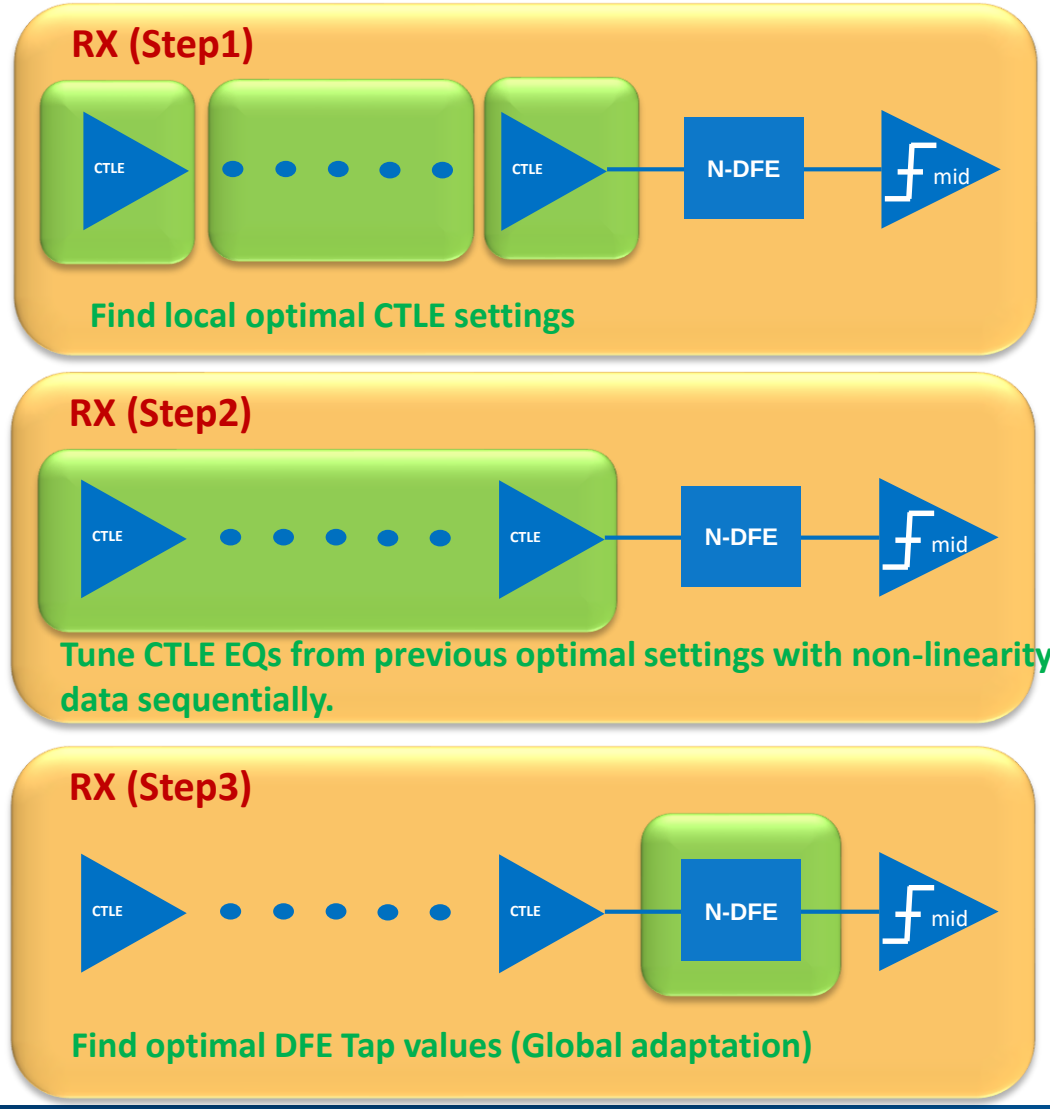
DFE NL behavior

- Slow loop response causes settling errors.
- Settling and offset errors are modeled in respect to each tap.

DFE step size/ range

- Each tap is modeled with a different step size and different tap weight range.

ADAPTATION



Global adaptation algorithm

- Use local optimal eq setting as an initial value.
- Tuning each EQ value based on the final SNR.

Statistical mode adaptation.

- Initial CTLE/DFE adaptation is done through init mode.
- Optimal EQ values are passed to bit-by-bit mode for further optimization for DFE.

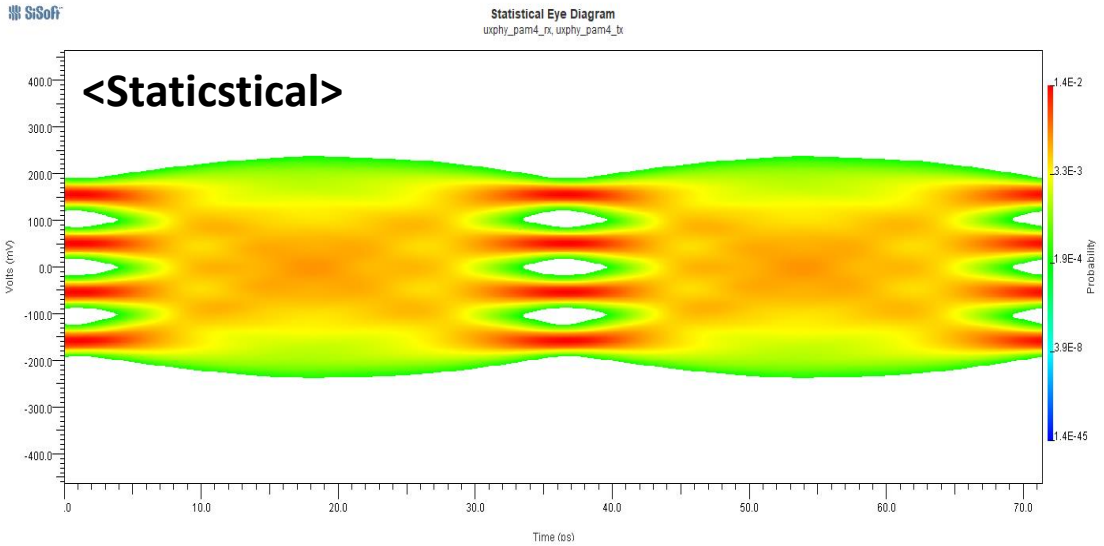
COM metrics used

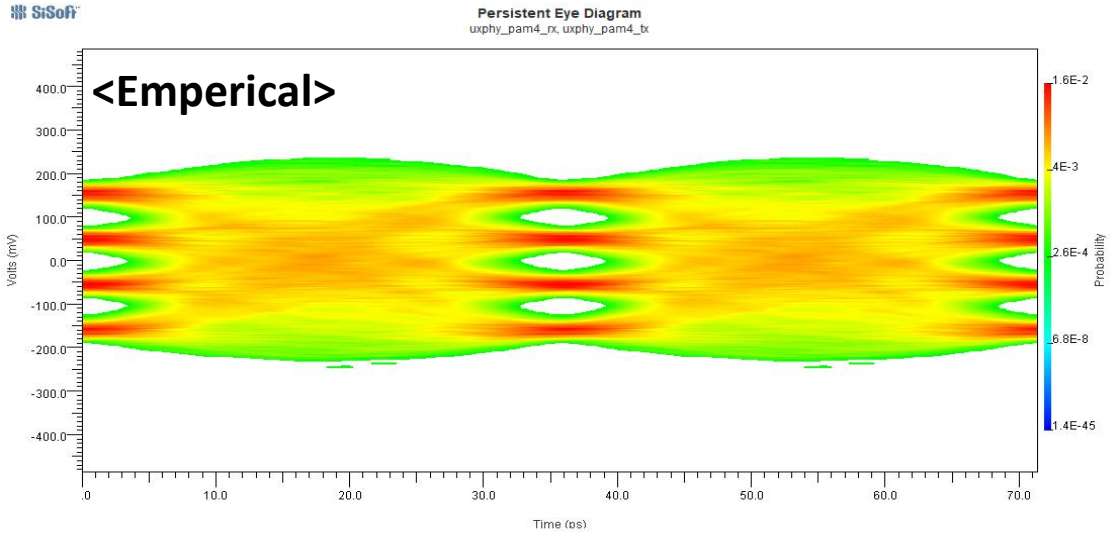
- Signal to noise ratio to optimize EQ adaptation.

Non Linearity aware adaptation.

- Applied to CTLEs and DFEs

Model analysis





Fast runtime

- This architectural abstract model runs more than x20 times faster then the detailed structural model.
- Fast adaptation with statistical mode optimization.

Excellent Correlation

- Statistical mode correlates well with bit-by-bit mode

Balanced eye opening

- Optimal EQ settings found.

Summary

- High speed IO modeling is extremely challenging due to the design complexity.

- A significant amount of time and effort is a MUST to capture the high quality design behavior.

- High quality IBIS AMI model generation is critical with faster run time.

- Help user to analyze their platform to identify any issues in a timely manor.

- Serdes Toolbox templates are used to make the modeling flow efficient.

- A huge amount of data is processed (# of corners, # of stages, # of configuration)
- Nice automation feature that helps to build a complicated model in an hour.

Q&A
